

REMARKS

Claims 1-3 were rejected as anticipated by Beneking. Claims 4-17 were rejected as unpatentable over Beneking. Applicant requests reconsideration. Independent claims 1, 6, and 18 include the limitation that the drains are coextensive in length. New claims 18 and 19 were added to include limitations of improved packing of multiple MOSFETS. The previously presented independent claims were previously amended to recite that the MOSFET is a triode MOSFET. Previously presented claims 15, 16, and 17 were previously amended to recite that the gate curvature is less than or equal to a quartercircle.

Beneking discloses a tetrode MISFET, not a MOSFET, having five electrodes, consisting of a source S, two drains D1 and D2, and discloses two control gates G1 and G3, and an interconnecting control gate G2. All of the present claims are directed to triode MOSFETs consisting of a single source, a single drain, and a single gate, where the drain and gate are coextensive in length, the gate curvature is defined by a radius from the source, and, the gate is less than 180 degrees. As is apparent from Beneking, the tetrode MIS-FETs are basically circular in configuration with opposing drains between which are disposed respective gate electrodes G1 and G3, an interconnecting gate G2. With all due respect, Beneking does not disclose a triode MOSFET.

///

1 The background of the present specification recites the prior
2 art circular designs of the triode configurations that lack an
3 ability to pack the MOSFETs in silicon for high density
4 integration, while also disclosing the prior art semicircular
5 serpentine configurations. The present invention enables high-
6 density integration of MOSFETs, similar to a stack of shallow
7 bowls, and hence, the particular 1/4 and 1/8 circular designs of
8 the preferred embodiments.

9
10 Beneking teaches prior art circular type design that does not
11 address the poor packing density problem. While Beneking does show
12 gates that are curved, one gate is slightly less than a semicircle,
13 that difference was slight to accommodate two separate gates with
14 opposing respective drains, but in total is still substantially a
15 circular design, and that difference is not directed to a triode
16 MOSFET as claimed. The claims 16 and 17 recite a limitation of a
17 quartercircle or less curvature that allows for efficient packing
18 integration of large numbers of MOSFETs while retraining the curved
19 gate structure, not taught by Beneking. The circular design of
20 Beneking teaches away from high-density packing. All of the claims
21 have now been limited to only triode MOSFETS, and hence, are not
22 anticipated by the tetrode MIS-FET device of Beneking. Beneking
23 does not address the problem of poor packing density of integrated
24 triode MOSFETS, which problem is solved by the present invention,
25 having curved gates in a triode MOSFET configuration.

26
27 The present invention is characterized as triode MOSFETs, each
28 of which having a gate with a defined radius and a defined arc-

1 length. This combination of features allows for improved
2 reliability with improved packing density. Beneking teaches away
3 from a curved signal triode MOSFET transistor and away from
4 improved packing density wherein transistors can be packed similar
5 to stacked bowls using gate curvatures.

6
7 The examination states that Beneking discloses "a gate
8 terminal (G1, G3)". How can G1 and G3 be equated to a singular gate
9 in a triode MOSFET without a suggestion to do so and in the
10 presence of clear teachings not to interconnect Beneking terminals
11 to form a single triode MOSFET?

12
13 The examination states that Beneking discloses "a second
14 terminal (2,3)". How can terminals 1 and 3 be equated to a singular
15 drain without a suggestion to do so and in the presence of clear
16 teachings not to interconnect drains to form a singular drain to
17 form a single triode MOSFET?

18
19 In Beneking there are three gate electrodes and two drain
20 (second) terminals, yet the examination simply equates them as one,
21 without any suggestion whatsoever do to so, the hallmark of
22 forbidden hindsight reconstruction, especially in the presence of
23 contrary teaching not to form a single transistor.

24
25 The difference between Beneking's tetrode MIS-FET and the
26 claimed triode is clear. The tetrode MIS-FET uses the control gate
27 G3 to directly or indirectly control the second gate G2, that in
28 turn controls the first gate G1. The claimed triode MOSFET has no

1 such direct or indirect control or interconnection. The examination
2 should recognize the difference between the tetrode MIS-FET and the
3 claimed triode MOSFET. In the triode MOSFET, there is a gate G
4 controlling current between a source S and a drain D. In the
5 tetrode MIS-FET, the gate (G3) is connected directly or indirectly
6 through the drain D2, to a control gate G2, that in turns controls
7 in part current flowing from that same source to another drain D1.
8 The use of the gate G3 to control current flow from the same source
9 S to another drain D1 is not the operation of a triode MOSFET.
10 Beneking device is not triode MOSFET. Beneking teaches the use of
11 the tetrode MIS-FET with an individual transistor. "In the
12 arrangement illustrated in Fig. 1, the electrodes D1, G2, G1, S are
13 electrodes of the TETRODE while the electrodes S, G3, D2 are
14 associated with the individual transistor". Clearly, in Figures 7,
15 8, and 9, Beneking shows how the tetrode device is interconnected
16 in application as three functioning MOSFETS, and not just one
17 MOSFET. As shown, the two control gates G1 and G3 are not connected
18 to each other, and hence, are controlling separate drains though
19 using a single source terminal disposed on a silicon chip. The
20 examination should acknowledge that Beneking teaches, in Figure 1,
21 an interconnected tetrode MIS-FET device interconnected to
22 effectively form three interconnected transistors, only one of
23 which is described as an individual transistor S, G3, and D2 having
24 a curved gate that is curved greater than 180 degrees. In all
25 exemplar forms in Beneking, the G1, S, D1 transistor in Figures 1,
26 2, 5 and 6 has a second control gate G2, and hence, is not a triode
27 MOSFET. Only the gate G3 is a gate that is disposed between a drain

1 D2 and the source S. The G1 and G2 gates, the drain D1 and source
2 do not form a triode MOSFET.

3
4 Figures 1 and 2 of Beneking do not show a gate (G3) that has
5 an arc-length less than 180 degrees. In Figures 5 and 6, the drain
6 D2 is not coextensive in length to the gate curvature of the gate
7 G3. The tetrode MIS-FET of Figures 1, 2, 5 and 6 do not enable high
8 packing densities of multiple like triode MOSFETS. Beneking does
9 not anticipate the present invention. Beneking teaches a device
10 having multiple drains, and multiple gates, and a source. Without
11 regard to the interconnection application teaching, the examination
12 equates all of these parts as a triode MOSFET, without a suggestion
13 to do so and explicitly contrary to the teachings of Beneking.

14
15 Beneking does teach a single transistor, S, G3 and D1, within
16 the tetrode device of Figure 1. However, in Figure 1, the G3 gate
17 has approximately 300-degree arc length that does not anticipate
18 the present invention. Beneking is directed to the use of MIS-FET
19 tetrodes for by two curved control electrodes for VHF and UHF
20 circuit applications, whereas the present invention is directed to
21 a triode MOSFET having a single reduced arc-length gate for
22 improved reliability and packing density.

23
24 Beneking dual control solution for UHF and VHF applications is
25 not related to the solution of high reliability and high packing
26 densities. The choice of 1/8 or 1/4 circle arc lengths as solutions
27 to poor reliability and low packing densities is not just a matter
28 of simple design choice, but is the solving of an unrelated

1 problem. The prior art choices were circles and semicircles that do
2 not provide for the improved reliability and improved packing
3 densities, and hence, the claimed invention is not just a matter a
4 design choice, but solves a problem heretofore unsolved.

5
6 Beneking does not teach a triode MOSFET having a curved gate
7 of defined curvature and arc length coextensive with a drain.
8 Beneking does not suggest a triode MOSFET of such limitations for
9 improved reliability and packing densities. Allowance of the claims
10 is kindly requested.
